

How To Setup and Build a Domain Controller

Building a Windows Server and setting up a domain controller on Windows Server can be a complex process, but here are the general steps to get you started:

1. **Install Windows Server:** To build a Windows Server, you will need to install the operating system. You can install Windows Server using a DVD or ISO file. During the installation process, you will be prompted to specify configuration settings such as the server name, time zone, and network settings.
2. **Configure Network Settings:** After the installation is complete, you will need to configure the network settings for the server. This will include configuring the IP address, subnet mask, and default gateway, as well as specifying the DNS servers to use.
3. **Install the Active Directory Domain Services (AD DS) Role:** To set up a domain controller, you will need to install the Active Directory Domain Services (AD DS) role. You can do this using the Server Manager or by using the PowerShell command-line interface.
4. **Promote the Server to a Domain Controller:** After installing the AD DS role, you will need to promote the server to a domain controller. This process involves specifying the domain name, creating a new forest, and configuring security settings. You can do this using the Active Directory Domain Services Configuration Wizard in the Server Manager or by using the PowerShell command-line interface.
5. **Configure AD DS:** After promoting the server to a domain controller, you will need to configure AD DS. This will include creating OUs, user accounts, and computer accounts. You can do this using the Active Directory Users and Computers snap-in in the Server Manager or by using the PowerShell command-line interface.
